## Abstract

**Background:** This systematic review and meta-analysis assessed the data from cohort studies that compared treatment with or without incretins and the incidence of breast cancer (BC) due to the current controversies.

**Methods:** PubMed, Scopus, EMBASE, Cochrane, ProQuest, Ovid, and Google Scholar were searched for relevant studies. A secondary analysis was conducted to compare the effect of glucagon-like peptide-1 receptor agonists (GLP-1RAs) and dipeptidyl peptidase-4 inhibitors (DPP-4Is) on BC development.

**Results:** The meta-analysis of four studies with 58,767 patients and 461,475 controls revealed that incretin-based therapies increase the incidence of BC insignificantly (risk ratio (RR)=1.23, 95% confidence interval (CI)=0.44–3.40;  $P=0.69$ ). The DPP-4I group significantly reduced the risk of BC compared to the GLP-1RA group (RR=0.43, 95% CI=0.32–0.59;  $P<0.00001$ ).

**Conclusion:** This study found no evidence of a substantial increase in BC incidence in patients with type 2 diabetes taking GLP-1RAs and DPP-4Is. However, DPP-4Is were less likely than GLP-1RAs to cause BC formation.

**Keywords:** Incretins, Breast cancer, Meta-analysis, Type 2 diabetes mellitus

## Introduction

Breast cancer (BC) is the most common cancer among women and the most common cause of women's cancer-related mortality.<sup>1,2</sup> It is expected that the global incidence of BC will approximately reach 3.2 million cases per year by 2050.<sup>3</sup> One of the major risk factors for the development of BC is diabetes mellitus (DM). According to a study, diabetic women had a 1.2 times higher probability of developing BC than non-diabetic women.<sup>5</sup> A meta-analysis in patients with BC revealed that preexisting diabetes is linked to poor disease-free survival and overall survival.<sup>6</sup> Similar to type 2 diabetes (T2DM), aging and obesity increase the incidence of BC.<sup>4</sup> The risk of BC was found to be increased in postmenopausal women with a higher body mass index.<sup>7</sup>

There has been a growing interest in determining whether antidiabetic drugs could affect cancer incidence in patients with T2DM. Antidiabetic medications may alter the risk of BC in diabetic patients. Rennert et al provided evidence of a strong reverse link between metformin usage and the risk of BC.<sup>8</sup> However, long-term use of insulin

glargine and sulfonylurea is linked to a higher BC risk in women with T2DM.<sup>9,10</sup> Incretin-based medications, including glucagon-like peptide-1 receptor agonists (GLP-1RAs) and dipeptidyl peptidase-4 inhibitors (DPP-4Is) are anti-hyperglycemic drugs that were first approved by the Food and Drug Administration (FDA) in 2010 for the management of diabetes. GLP-1RAs mainly regulate postprandial glucose metabolism by stimulating pancreatic insulin production while decreasing glucagon secretion.<sup>11</sup> Because of their modest efficacy in decreasing glucose and minimal risk of hypoglycemia and weight gain, these medications are routinely used in individuals with T2DM.<sup>12</sup> These agents could also lower glucose levels by reducing gastrointestinal absorption and motility, suppressing appetite, delaying gastric emptying, and improving lipid metabolism.<sup>13,14</sup> On the other hand, DPP-4Is suppress DPP-4, so they help to stimulate post-meal insulin production by preventing endogenous GLP-1 breakdown.<sup>15</sup>

There are conflicting results about the relationship between incretin-based drug usage and BC. According

to the FDA and the European Medicines Agency, GLP-1 analogues are linked to an elevated BC risk.<sup>16</sup> GLP-1 receptors have been found on normal mammary gland tissue in preclinical research, suggesting that GLP-1 analogues could stimulate early BC formation via fibroblast growth factor 7.<sup>17</sup> Furthermore, the GLP-1 receptor was more generally discovered in BC tissue than in normal breast tissue, noticeably in diabetic patients.<sup>18</sup> Some safety concerns about BC events have emerged from randomized controlled trials (RCTs) among patients with diabetes.<sup>19-21</sup> In a real-world setting, however, a prospective cohort study found no link between the usage of liraglutide and female BC.<sup>22</sup> Likewise, other studies reported a potentially protective role of DPP-4Is in BC after long-period consumption.<sup>23,24</sup> In a cohort study, however, overall survival did not favor the patients with BC taking DPP-4Is.<sup>25</sup> Therefore, it is uncertain if incretin-based therapy raises the risk of BC.

Regarding the inconsistent results and existing data raising concerns about BC incidence with incretin-based drugs, we aimed to conduct a meta-analysis of all cohort studies comparing incretin-based therapies with other antidiabetic medications among women with T2DM to assess the risk of BC. In addition, we tried to compare the BC risk using DPP-4Is and GLP-1RAs.

## Methods

### Search Strategy

Two authors (MO and SR) independently conducted a thorough literature search to identify all cohort studies that examined the connection between incretin-based medication and BC risk in T2DM women. The literature search was conducted on PubMed, Scopus, EMBASE, Cochrane, ProQuest, Ovid, and Google Scholar. Research keywords included “incretin”, “incretin-based therapy”, “glucagon-like peptide 1 receptor agonist”, “GLP-1 receptor agonists”, “GLP-1RAs”, “liraglutide”, “semaglutide”, “exenatide”, “lixisenatide”, “dulaglutide”, “albiglutide”, “dipeptidyl peptidase-4 inhibitor”, “DPP-4 inhibitors”, “DPP4i”, “sitagliptin”, “vildagliptin”, “saxagliptin”, “alogliptin”, “linagliptin”, “type 2 diabetes mellitus”, “T2DM”, “breast neoplasm”, and “breast cancer”. It should be noted that only English-language publications were considered.

### Inclusion Criteria

The current study was carried out to assess the link between incretin-based medicines (exposure) and the development of BC in T2DM women (outcome). This meta-analysis included studies that fulfilled the following criteria: (a) cohort studies, (b) being done in patients with T2DM, (c) comparing incretin-based therapy to other glucose-lowering medicines, and (d) assessing BC incidence. Publications that compared DPP-4Is or GLP-1RAs with other active antidiabetic agents were included. Two authors (MO and SR) independently assessed the title or abstract and the full articles to see whether each

article met the qualification criteria for ultimate inclusion. Moreover, consensus between the two investigators and a third reviewer (FD) was obtained to resolve conflicts.

### Exclusion Criteria

The papers that met the following criteria were excluded: (a) non-cohort studies (b) case reports, (c) review articles, (d) conference abstracts, (e) animal studies, (f) articles that were not accessible after mailing for full-text request from the corresponding author for two times, (g) articles that did not provide enough data for analysis, and (h) duplicate articles.

### Data Extraction and Quality Assessment

Each title and abstract were initially screened, and if they met the inclusion criteria, they were then thoroughly reviewed in accordance with the eligibility criteria. The characteristics of the included studies were captured using a data extraction form (author's name, study year, location and period of the study, sample size, study type, baseline information of the patients, type of treatment, duration of treatment, and results for effectiveness and harm outcomes).

The Newcastle-Ottawa Scale's (NOS's) risk of bias tool was used for the methodological quality assessment of the included cohort studies.<sup>26</sup> It was employed to evaluate cohort studies for quality of selection (selection of the non-exposed cohort, representativeness of the exposed cohort, and ascertainment of exposure), comparability (confounding), and outcome (assessment of outcome, length, and adequacy of follow-up of cohorts). A study might receive a maximum score of 9 points. We determined that studies getting 5 points or higher are of moderate to good quality. Further, the quality of each included study was independently appraised by two authors (MO and ZT). Disagreements between the two authors were resolved by consensus with two other investigators (FD, MM). Following the conclusion of the quality assessment, data extraction started by assessing the full text of publications.

### Statistical Analysis

This meta-analysis was performed to assess the risk of developing BC in women with T2DM using incretin-based drugs compared to other anti-diabetic medications. Furthermore, a second analysis was conducted, including studies that compared the effects of DPP-4Is and GLP-1RAs on the risk of BC. Based on the number of BC incidents in each group, the risk ratio (RR) and 95% confidence intervals (CIs) were calculated. Moreover, the  $I^2$  statistic was used to assess the degree of heterogeneity among the studies, and when the heterogeneity was high, a random-effects model was used. Otherwise, studies with low statistical heterogeneity were performed using fixed-effects model.<sup>27</sup> All reported  $P$  values were 2-sided, and  $P < 0.05$  was considered significant, and RevMan

5.3 (Review Manager, Version 5.3; The Cochrane Collaboration, 2014) was used for statistical analysis.

**Results**

**Study Selection**

Database searches yielded a total of 985 studies, of which 647 studies remained after removing duplicate records. Then, 596 studies were excluded as they were irrelevant articles, reviews, case reports, animal models, cell line studies, conference abstracts, and non-English articles by screening titles and abstracts, leaving 51 studies for full-text evaluation. Afterward, the full texts of the remaining articles were assessed in detail to evaluate if they met the inclusion criteria. The systematic review and meta-analysis included the final four studies that met the inclusion criteria. The Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) flowchart of the study is presented in Figure 1. Overall, 520242 participants were included after assessing the type, title, abstract, and full text of studies searched up to December 2021.

**Quality Assessment of Included Studies**

In the systematic review, all included studies were cohort studies. Table 1 presents the study characteristics and

results of the included studies. All four studies were examined by NOS and received a score of 6 points or higher, indicating that they were of moderate to good quality (Table 2).

**Meta-analysis Results**

The number of BC events in each treatment arm (active medicine or placebo/non-incretin comparator drugs) was imputed for the primary analysis. Then, the RR ( $\pm$ 95% CI) was computed. The heterogeneity statistic Q was used to evaluate heterogeneity, while  $I^2$  was used to quantify it. The results demonstrated that the studies have a significant level of heterogeneity ( $I^2=98\%$ ). The analysis showed that compared with antidiabetic drugs or another placebo, incretin-based therapies non-significantly increased the incidence of BC (RR= 1.23, 95% CI: 0.44–3.40;  $P=0.69$ ), as depicted in Figure 2.

A secondary analysis was performed to compare the effect of DPP-4Is and GLP-1RAs on BC risk. The results of the analysis indicated that BC formation is significantly lower with the use of DPP-4Is than using GLP-1RAs (RR=0.43, 95% CI: 0.32–0.59;  $P<0.00001$ ). There was also no statistical significance in between-study heterogeneity ( $I^2=0\%$ ,  $P=0.79$ ), as illustrated in Figure 3.

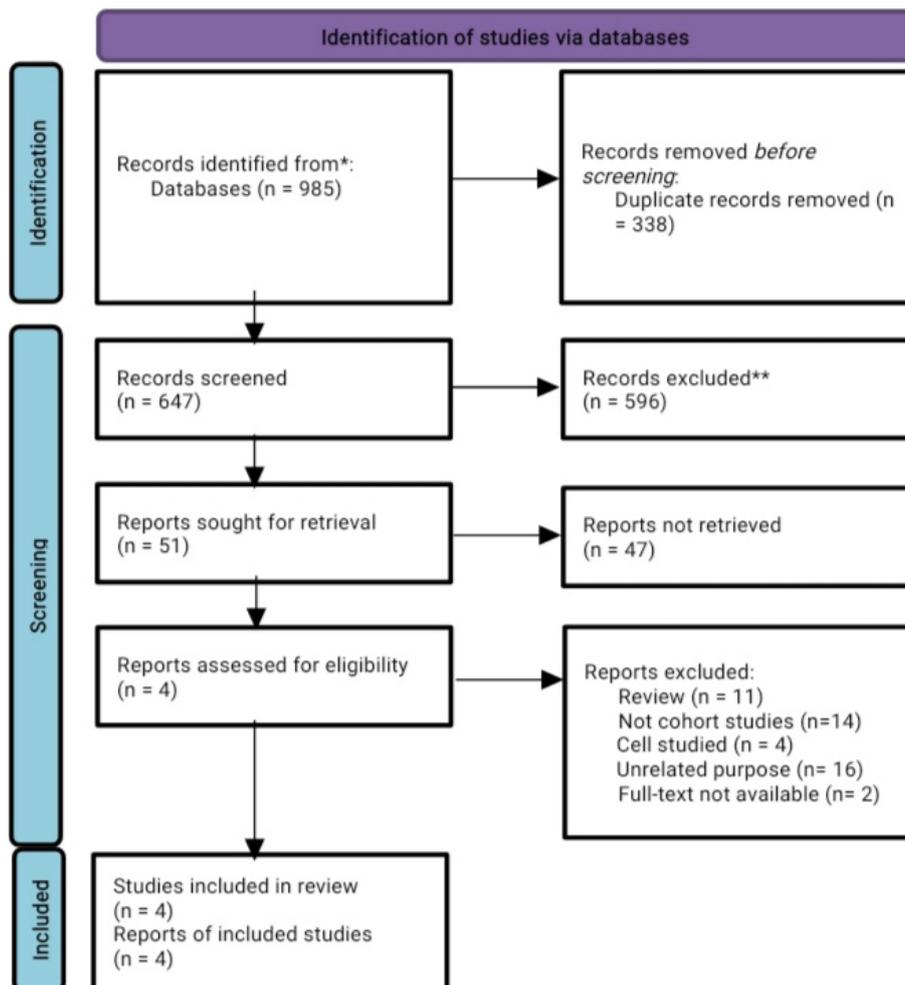

Figure 1. Flow Diagram of the Study Selection Process

**Table 1.** Summary of the Included Studies in the Systematic Review

Author	Region	Year	Study Beginning and Follow-up Period	Sample	Instrument	Results	HR (95% CI)	NOS
Hicks et al <sup>22</sup>	Canada	2016	1 January 2007 and 31 March 2015 to 31 March 2016	498 users of GLP-1RAs*, 2,422 users of DPP-4Is*, 42,064 users of other glucose-lowering drugs	cox proportional hazards regression models	Among GLP-1RAs and DPP-4Is users, 31 and 68 patients had BC, respectively. GLP-1RAs were not linked to an elevated risk of BC risk in contrast to DPP-4Is. (Incidence 4.4 v 3.4 per 1000 person-years; HR= 1.40 (95% CI=0.91 to 2.16)).	Crude incidence 3.5 (95% CI= 3.3 to 3.8) per 1000 person-years	8
Tseng et al <sup>23</sup>	Taiwan	2016	1999 and 2010 to 31 December 2011	32,457 users and 396,021 never-users of sitagliptin	Cox regression models	78 users and 2204 never-users had BC diagnoses. Sitagliptin may lower the incidence of BC in women with T2DM, particularly one year following use.	HR* = 0.718 (95% CI, 0.573-0.901)	7
Santella et al <sup>28</sup>	Canada	2020	1 January 2007 to 31 January 2018	5,510 users of GLP-1RAs and matched 5,510 users of comparator drugs	Cox proportional hazard models	Among GLP-1RA users, 65 new cases of BC were diagnosed, compared with 50 patients in the comparator group. (Incidence rates in the GLP-1RAs group were 3.9 [95% CI=3.0, 4.9] and 3.0 [95% CI=2.2, 3.2] in the comparator group per 1,000 person-years). According to the supplementary content, among DPP-4Is users, there were 27 BC cases. BC diagnosis rose with GLP-1RAs weight reduction groups, especially in those who lost >10% of their body weight.	At least 10% weight loss (HR = 1.8, 95% CI= 1.1, 2.8) for >10% weight loss (HR = 2.9, 95% CI= 1.2, 6.9)	8
Funch et al <sup>29</sup>	USA	2018	1 February 2010 to 30 November 2014	17,880 users of liraglutide and 17,880 matched users of all comparator drugs		Among the matched liraglutide and "all comparator", there were 85 and 94 BC cases, respectively. Liraglutide use did not increase the risk of BC.	RR=0.90 (95% CI: 0.67–1.22)	6

Note. HR: Hazard ratio; NOS: Newcastle-Ottawa Scale; CI: Confidence interval; BC: Breast cancer; RR: Relative risk; GLP-1RAs: Glucagon-like peptide-1 receptor agonists; DPP-4Is: Dipeptidyl peptidase-4 inhibitors.

**Table 2.** NOS Risk of Bias Tool for the Methodological Quality Assessment of the Involved Studies

Study ID	Selection	Comparability	Outcome	Total Score
Hicks et al <sup>22</sup>	4	1	3	8
Tseng <sup>23</sup>	4	1	2	7
Santella et al <sup>28</sup>	3	2	3	8
Funch et al <sup>29</sup>	3	1	2	6

Note. NOS: Newcastle-Ottawa Scale.

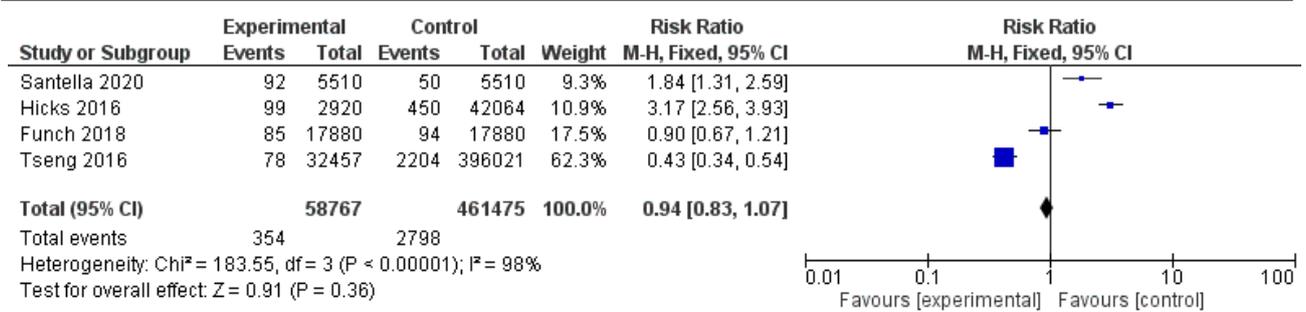

**Discussion**

Incretin-based glucose-lowering medications (GLP-1RAs and DPP-4Is) are now routinely used to effectively treat T2DM. The advantages of their administration in diabetes are promoting weight loss (GLP-1RAs) or not affecting body weight (DPP-4Is), as well as low hypoglycemia rates.<sup>11,30</sup> Clarifying the effect of the glucose-lowering drug on tumor biology is important because the cancer risk increases in patients with T2DM.<sup>31</sup> Currently, a rising number of studies are focusing on the preventive function of incretin-based therapy in neurodegenerative disorders against pathophysiological processes.<sup>32</sup> Moreover, incretin reduces diabetic microvascular complications, non-alcoholic steatohepatitis, and non-alcoholic fatty liver disease. GLP-1RAs were found to significantly reduce stroke, severe adverse cardiovascular events, and death from any cause.<sup>33-35</sup> Despite the preventive effects of incretins, more research is needed on the cancer-related risk of these treatments.<sup>36,37</sup>

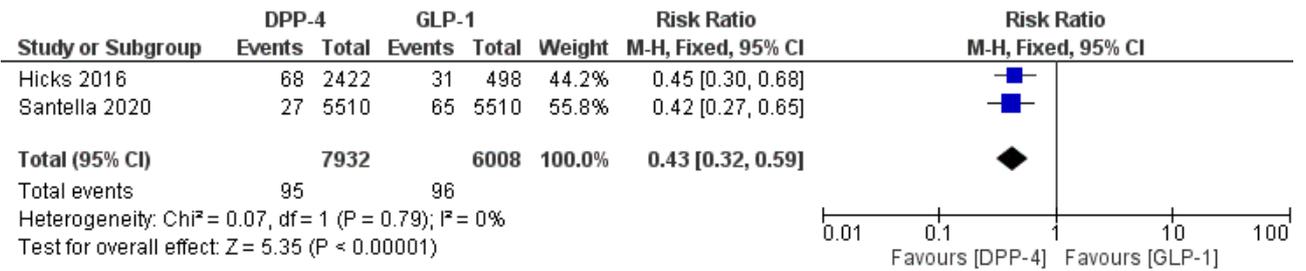

The debate about the long-term safety of incretin-based drugs is accompanied by conflicting results. A systematic review reported that once-weekly GLP-1RAs do not

increase the risk of tumor occurrence.<sup>38</sup> Additionally, DPP-4Is were not related to an increased risk of cancer at a specific site.<sup>24</sup> However, both studies were limited to a small sample size and suggested conducting studies with a larger sample and a more extended period of follow-up to determine the long-term cancer risk. According to an observational study, in individuals with T2DM, sitagliptin may act as a preventive measure in the establishment of BC.<sup>23</sup> However, Takigami et al demonstrated that the activation of the GLP-1 receptor might be related to the onset, progression, and treatment resistance of BC in female diabetic patients.<sup>18</sup> Moreover, GLP-1 receptor agonists raised the risk of BC. In contrast, liraglutide could significantly lower serum tumor marker levels and apoptosis-related molecules in the breast tissues of patients with BC and diabetes.<sup>39</sup>

Likewise, in vitro studies have yielded conflicting outcomes. Increasing evidence suggests that incretin agents could have tissue-protective effects through apoptosis induction and anticancer features.<sup>40-42</sup> Iwaya et al investigated the influence of GLP-1 against BC models, including Michigan Cancer Foundation-7 (MCF-7), MDA-MB-231 and KPL-1 cell lines, and human BC tissue. GLP-1RAs such as exendin-4 greatly decreased BC cell numbers and prevented their proliferation. Moreover, exendin-4 attenuated the growth of BC via the inhibition of nuclear factor kappa-light-chain-enhancer of activated B cells (NF-κB) activation both in vitro and in vivo.<sup>43</sup> According to another study, depending on the cell population concentration, liraglutide could be both a stimulator and an inhibitor of MDA-MB-231 cell proliferation.<sup>44</sup> Moreover, researchers have indicated

**Figure 2.** Forest Plot of Comparison: BC Risk in Women with T2DM Who Were Treated with Incretin-based Medications (GLP-1RAs or DPP-4Is) Versus Other Drugs. Note. BC: Breast cancer; T2DM: Type-2 diabetes; GLP-1RAs: Glucagon-like peptide-1 receptor agonists; DPP-4Is: Dipeptidyl peptidase-4 inhibitors

**Figure 3.** Forest Plot of Comparison: Analysis of BC Risk in Women with T2DM and Comparing Treatment with GLP-1RAs and DPP-4Is Drugs. Note. BC: Breast cancer; T2DM: Type-2 diabetes; GLP-1RAs: Glucagon-like peptide-1 receptor agonists; DPP-4Is: Dipeptidyl peptidase-4 inhibitors

that DPP-4 signaling can promote epidermal growth factor-induced epithelial cell transformation and mammary tumorigenesis via the induction of peptidyl-propyl cis-trans isomerase 1 expression, suggesting that sitagliptin as a DPP-4I could be useful for the treatment of breast tumors in patients with T2DM.<sup>45</sup> On the contrary, cell lines analysis suggested that DPP-4 inhibition could accelerate BC metastasis by inducing epithelial-mesenchymal transition through C-X-C motif chemokine 12/C-X-C receptor4 (CXCL12/CXCR4)-mediated mammalian target of rapamycin activation and promote chemoresistance in BC cells.<sup>46,47</sup> However, using DPP-4I did not enhance the risk of metastases in an observational study on diabetic patients with BC.<sup>48</sup> A recent meta-analysis of randomized controlled trials revealed favorable outcomes for treatment with DPP-4I and BC development.<sup>49</sup> Moreover, the weight-lowering effects of GLP-1RAs may increase BC incidence by easing the process of finding already present breast lumps, leading to early diagnosis of cancer.<sup>19,28</sup> Furthermore, postmenopausal women who lose weight over the long term have a lower risk of BC development.<sup>50</sup>

The current study investigated the impact of incretin-based medication administration on BC incidence in women with T2DM using a meta-analysis of cohort studies. To this end, four cohort studies were included: two studies found no association between incretins and BC incidence, one indicated protective roles against BC, and one showed an increase in BC detection with incretin-based therapies.<sup>22,23,28,29</sup> Due to the discordant results regarding the connection between incretins and BC, it was necessary to conduct a systematic review and meta-analysis of studies with longer-term follow-up.

This study indicated that in comparison to either placebo or active antidiabetic drugs, incretins are not linked to an increased BC risk, implying that there was no worrisome rise in the risk of BC during treatment with incretins. The results of the present meta-analysis are consistent with the findings of a previous systematic review and meta-analysis of RCTs conducted by Piccoli et al who analyzed the risk of BC in treatment with GLP-1RAs for diabetes and obesity.<sup>51</sup> In another meta-analysis, the pooled estimate of observational studies on BC indicated that using DPP-4 inhibitors reduces the risk of cancer which was statistically significant (HR (95% CI): 0.76 (0.60-0.96)).<sup>24</sup> Besides, based on the limited cohort studies on incretin-based drugs, the results of the present study show no evidence of a significant rise in the incidence of BC in T2DM women taking incretin-based drugs from both the GLP-1RAs and DPP-4Is classes. The same results were found using a second analysis that classified the studies by comparing the effect of GLP-1RAs and DPP-4Is on BC risk. However, DPP-4Is were substantially associated with a lower risk of BC formation compared to GLP-1RAs. The heterogeneity test also showed a high heterogeneity among included studies, which could be a key component in the meta-analysis results. The limitation of our study lies in the limited rate of incretin use. Since the mechanisms of action of these two medication groups differ, future studies such as DPP-4I and GLP-1RA agonists should be conducted independently to improve the accuracy of the results. One of the strengths of the current review is that all of the included studies were cohort studies that, to our knowledge, have not been previously summarized in a systematic review. As the development of cancer occurs over a long period and patients participating

in RCTs are healthier than general world patients, the extended duration of the studies included in the review makes it more likely to determine the risk of neoplasms with incretin-based therapies. Another strength is that we compared the effect of DPP-4Is and GLP-1RAs on the risk of BC, which has not been previously assessed.

### Conclusion

In summary, findings from this study indicated that the use of DPP-4Is and GLP-1RAs is not associated with an increased BC risk. Furthermore, the DPP-4I group had a decreased risk of BC than the GLP-1RA group. Altogether, these data offer clinicians and patients further drug safety information about this potential relationship among people with T2DM.

### Ethics statement

This study was approved by the Ethics Committee of Tabriz University of Medical Sciences and conducted in accordance with the Helsinki Declaration. Date: 2020-11-30, Number: IR.TBZMED.VCR.REC.1399.311.

### Disclosure of funding source

The authors declare that no funds, grants, or other support were received during the preparation of this manuscript.

### Conflict of interests declaration

The authors have no relevant financial or non-financial interests to disclose.

### Acknowledgments

The authors would like to thank the staff members of the Student Research Committee, Tabriz University of Medical Sciences for their kind support (Project number: 65786).
